What is an Alarm? (per ISA-18.2)

An alarm is an audible and/or visible means of indicating - There must be an indication of the alarm. An alarm limit can be configured to generate control actions or log data without it being an alarm.

to the operator - The indication must be targeted to the operator to be an alarm, not to provide information to an engineer, maintenance technician, or manager.

an equipment malfunction, process deviation, or abnormal condition - The alarm must indicate a problem, not a normal process condition. (e.g., pump stopped, valve closed).

requiring a response - There must be a defined operator response to correct the condition and bring the process back to a desired (safe and/or productive) state. If the operator does not need to respond, then the condition should not be an alarm.

The Alarm Rationalization Process

Alarm Rationalization
- The process of reviewing potential (candidate) alarms against the criteria defined in the alarm philosophy to ensure they are necessary, and to define/document their design in a master alarm database (MADB).

Alarm Validation Checklist
- Does it indicate a malfunction, deviation or abnormal condition?
- Does it require a timely operator action in order to avoid defined consequences?
- Is it unique (or are there other alarms that indicate the same condition)?
- Is it the best indicator of the root cause of the abnormal situation?

Alarm Objective Analysis
- Consequence – The immediate & direct result of the abnormal situation identified by the alarm and not a possible consequence requiring other failures.
- Corrective Action – Steps to be taken to correct the abnormal situation (acknowledging the alarm does not count).
- Confirmation – Document other process measurements that the operator can look at to confirm/verify that the alarm is real.
- Operator Response Time – The time from the activation of the alarm until the last moment the operator action will prevent the consequence.

Alarm Classification
- A method for organizing (grouping) alarms based on common characteristics and requirements (e.g., training, testing, MOC, reporting).

Alarm Limit (Setpoint) Determination
- Far enough away from the consequence threshold so that operator has adequate time to respond.
- Not too close to normal operating conditions that alarms are triggered as a result of normal process variation.

Advanced Alarming
- Advanced Alarming – Additional layers of logic, programming, or modeling used to modify alarm attributes (dynamically).
- Document the states, conditions, products or phases where...
  - Alarm attributes (limit, priority) should be different from steady state.
  - Alarm should be suppressed from the operator.

Master Alarm Database (MADB)
- The authorized list of rationalized alarms and associated attributes.

The Alarm Rationalization Process

Hazard Identification and LOPA Reviews, Incident Investigations, Licensor Recommendations etc.

Potential Alarms to be Rationalized

Existing Alarm Database

Select the alarm to be rationalized

Is the alarm valid / justified?

Yes

No

Does the alarm have sufficient basis?
(Alarm Objective Analysis)
- Likely Cause(s)
- Consequence of Inaction
- Corrective Action(s)
- Operator Response Time Confirmation

Yes

No

Prioritize the Alarm
(Based on Time to Respond, Potential Consequences)

Classify the Alarm

Specify the Alarm Attributes
- Alarm Limit (Setpoint)
- Alarm Type
- Deadband, On / Off Delay
- Alarm Message

Assess Need for Special Handling
(Advanced Alarming)
- First-Out Alarming
- Use of Common Alarm
- State-Based Suppression
- Alarm Flood Suppression
- State-Based Alarming
- Alarm Routing

Alarm Response Procedures

Document Alarm Design and Decisions
